**ABSTRACT**

*The present study details a theoretical-conceptual model, scoping the interrelations between antecedents (academic buoyancy, emotional and physiological states, task value), cognitive processes (habitual action, critical reflection), and adaptive outcomes (academic engagement, academic achievement) in the context of educational psychology. 294 (151 men, 143 women) first-year university students participated in this study. Likert-scale inventories were administered to students and used to elicit relevant data; for example, Academic Buoyancy Scale and the Task value sub-scale of the Motivated Strategies for Learning Questionnaire (MSLQ). Academic achievement was collated from students' overall marks in the unit educational psychology. Structural equation modeling (SEM) analyses supported, in part, the conceptual model with some statistical significant paths. In general, on the basis of the findings yielded, there are significant implications for research development and educational practices. From the results of the study, it was discovered that a heightened sense of critical reflection enables students to achieve and excel, academically. One of the recommendations was that Educators should endeavour to consider students' mastery and performance –based approaches to academic learning by encouraging positive outcomes rather than making attempts to resolve potential detrimental consequences, which had been found to be more cost-effective and has a number of educational and social benefits.*

**KEYWORDS: Antecedents, Cognitive Processes, habitual action, critical reflection, academic achievement, academic engagement, academic buoyancy**

---

**Introduction**

Quality learning, entailing interest, improvement of skills, and mastery, is an important component for recognition. Academic learning, in this sense, emphasizes other related attributes, such as intellectual curiosity, personal best, and the inner desire for gratification. Educators and researchers often seek to explore theoretical orientations and psychosocial factors that explain proactive engagement and individuals' academic successes (Fenollar, Roman, and Cuestas 2007). Cognitive (e.g., processing strategies) and motivation (e.g., intrinsic motive) tenets, for example, may account for why some individuals achieve and surpass others in educational

contexts. This inquiry into the impact of quality learning, from our point of view, is advantageous as it focuses on non-deficit, positive reasoning – for example, how we can assist and enhance students’ engagement. The present study, consequently, seeks to explore a number of theoretical orientations that could account for university students’ learning in achievement contexts. A synthesis of the literature indicates there are a number of constructs that contribute to the prediction and enhancement of adaptive outcomes and positive behaviors. The main research objective, in particular, entails the optimization of students’ learning and performance outcomes via cognitive and motivation processes. The theoretical-conceptual model that have been articulated, similar to some recent studies (e.g., Fenollar, et al., 2007; Lau, Liem, and Nie 2008; Martin, 2010 and Liam, Lau and Nie, 2008), is significant for its amalgamation of three major, sequential processes: (i) antecedents (*academic buoyancy, emotional and physiological states, and task values*), (ii) cognitive processes (*habitual action and critical reflection*), and (iii) adaptive outcomes (*engagement and academic achievement*). This conceptualization unifies inquiries pertaining to relations between academic achievement and non-cognitive processes of learning (e.g., task value) (Martin and Marsh, 2008; Liem, et al., 2008; Eccles, et al., (1983), and the relations between cognitive processes and adaptive outcomes (e.g., achievement) (Simons, Dewitte, and Lens, 2004; Martin and Marsh, 2009). To our knowledge, very few research studies have yet unified the two mentioned research strands within one study. Such unification, in our view, may shed important insight into the trajectories amongst the various theoretical frameworks of learning. The theoretical-conceptual model proposed for this investigation details the intricacy of both cognitive and non-cognitive process outcomes in achievement contexts. A hypothesized structural relations, illustrates the predictive and explanatory effects of academic buoyancy, emotional and physiological states, and task values on academic engagement and achievement, via habitual action and critical reflection. Findings obtained from the present study may provide a basis for discussion and continuing research development, cross-culturally, into students’ processes of effective learning. One notable avenue of inquiry, for example, entails the potential to situate our hypothesized model in other socio-cultural contexts.

### ***Academic Buoyancy, Emotional and Physiological States, and Task Values***

Research into student learning, encompassing both cognitive and motivational theories, has involved conceptualizations (Fenollar, et al., 2007; Lau, et al., 2008; Martin, 2010 and Liam, et al., 2008) that depict intricate interrelationships, whereby a number of constructs serve as antecedents of adaptive outcomes. Examination of the empirical literature indicates some notable psychosocial factors and motivational processes that could serve as potent antecedents. In the context of the present investigation, we choose to explore three main theoretical constructs: academic buoyancy, task values, and emotional and physiological states. This emphasis, from our point of view, is significant, given very few, if any, studies that have investigated these antecedents, in totality, within one theoretical-conceptual framework. Martin and Marsh (2008a) defined academic buoyancy as “an individual’s capacity to successfully overcome setbacks and challenges that are typical of the ordinary course of everyday” (e.g., poor performance, competing deadlines, performance pressure, difficult tasks) (Martin and Marsh, 2008). The theoretical grounding of academic buoyancy is based on the belief that resilience, and construct that is similar in nature and characteristics, has limited applicability and does not cater for the challenges and adversities that are typical of daily academic life (Martin and marsh, 2009). There

is evidence, albeit limited at present, to suggest that academic buoyancy influences both educational (e.g., enjoyment of school, class participation) and psychological (e.g., general self-esteem, self-efficacy) and outcome measures (Martin, et al., (2010).

Martin and Marsh's (2008) longitudinal study, for example, has yielded some preliminary findings to show the predictive and explanatory powers of academic buoyancy in educational settings (e.g., Time 1 academic buoyancy influenced Time 2 anxiety ( $= -.10, p < .01$ )). The inclusion of academic buoyancy as an antecedent is sound, given its characteristics and the fact that existing empirical findings have attested to its potency. Structural validity established in the present study would provide empirical evidence, supporting previous research investigations regarding the characteristics and impact of academic buoyancy. In a similar manner, the inclusion of task values, grounded within the expectancy-value theoretical framework (Eccles 1983), has been proposed as an antecedent. Eccles and her colleagues identified several types of subject task values, notably: attainment value or importance, intrinsic value, and utility value or usefulness of the task. There is extensive research (Liem, et al., 2008) that shows the positive contributions of the various types of task values on learning and achievement-related outcomes and behaviors. A learning task that has utility values, may assist students beyond the immediate situation of a classroom. Tasks with intrinsic values, likewise, are interesting and may stimulate appreciation and intellectual curiosities, mediating students' social interactions, proactively in classroom and non-classroom settings (Hulleman, et al., 2008). The productiveness of task values, as stipulated by the expectancy-value theoretical framework and previous research findings indicates the potential of this construct as a predictor of achievement-related outcomes. The valuing of a learning task or activity (e.g., how to filter rainwater) for its perceived usefulness or importance may result in students adopting a favorable mindset, facilitating them to approach learning with a view to improve and develop personal competence. Consequently, arising from this personal attention and approach to learning, students may actively seek out critical reflective skills for assistance. This proposition is in consonance with existing research studies, which have reported the positive associations between task value and various cognitive-motivational constructs: achievement goal types, choice behaviors, persistence, and effort (Wigfield, and Eccles, 2000). Similarly, in relation to learning approaches, Liem, et al. (2008) found that task value influenced both deep ( $= .22, p < .05$ ) and surface ( $= .37, p < .05$ ) learning approaches indirectly, via mastery goals. Subjective task value, especially in terms of intrinsic values e.g., "I am very interested in the content area of this subject": may espouse and relate to intrinsic motivation. Students who inquire and learn a subject matter because of its intrinsic value (e.g., learning how to filter rainwater) may, in this analysis, partake and engage in related exercises and activities for their own sake. What this means then is that subjective task value may feature as an important determinant of positive behaviors and adaptive outcomes.

Emotional and physiological states, according to social cognitive theory (Bandura, 1986), may operate as an important source of information in the cognitive appraisal of capabilities. Affective responses, such as anxiety, apprehension, and mood swing are indicative of one's own resolute, capableness, and vulnerability to deal with dysfunctions and educational-related tasks, situations, and events (e.g., a student's high state of anxiety before a final exam in mathematics). Negative affective responses such as anxiety, similarly, tend to weaken academic achievement and have been shown to relate inversely with self-beliefs (Education Journal 2014) for learning (e.g., personal self-efficacy). Given their characteristics, we expect to find emotional and physiological states to relate inversely with critical reflection. Students who demonstrate positive affective

responses (e.g., happiness) and are well-versed, academically, would feel more buoyant and confident to partake in learning activities and confront challenges with an open mindset. It is also expected that this informational source would associate positively with habitual action. Students who are inefficacious and exhibit negative affective responses (e.g., exam anxiety) would tend to expend minimal effort, avoid working (e.g., adopting work-avoidance goals), and gravitate towards strategies (e.g., seeking help) that support habitual action.

### *Internal Cognitive Processes*

The intricacy of academic learning also involved the operational nature of internal cognitive processes, which could act in tandem with other psychosocial factors and/or motivational constructs to influence adaptive outcomes. A theoretical review indicates there are a number of cognitive processes that account for students' learning in achievement contexts, for example: effort expenditure, persistence, and study processing strategies. We choose, in this case, to explore two contrasting processing strategies: habitual action versus critical reflection. These two dichotomous constructs, based on Kember, et al.'s work, are grounded, theoretically, within the framework of reflective thinking. This analysis connotes that individuals, in their quest to learn and master a subject matter, would adopt and exhibit a myriad of cognitive skills relating to reflective thinking. Habitual action is more simplistic, whereby learning is automated and very little conscious thought is involved (e.g., solving arithmetic- mathematics problems that involve addition and subtraction). In this sense, according to Kember, et al. (2000), habitual action indicates very little, if any, reflection in the learning process. Critical reflection, in contrast, is more complex and entails a cognitive transformation in one's ability to critique presuppositions and prior learning. Development of critical reflection skills, in particular, enables individuals to make complex hypotheses for further investigation and addressing. Both habitual action and critical reflection, are opposite in scope and characteristics, resulting in differing patterns in relationships with other cognitive-motivational variables. Relationships between habitual action and critical reflection and other variables, however, have been limited in terms of empirical validation. Within the past decade, for example, very few research studies have explored habitual action and critical reflection and their impacts in educational contexts. Apart from Kember, et al.'s (2000) original study, which focused on the psychometric properties of the Reflective Thinking Questionnaire (RTQ), the works of Phan (2007,2009) and Leung and Kember (2003) have been relatively prominent. Characteristics of habitual action and critical reflection, and construct validity of the RTQ, have been verified with Leung and Kember's (2003) study. The important question then, for consideration, is whether and to what extent both habitual action and critical reflection could feature as central processes in student learning. Similarly, in terms of advancing our understanding of the characteristics of these two cognitive constructs, it would make logical sense to consider their potential associations with academic buoyancy, emotional and physiological states, and task values. This aspect of the present research inquiry is exploratory in nature, given there is limited research, at present that has delved into the antecedents of habitual action and critical reflection (Phan, (2007). Does academic buoyancy, as a form of motivation, associate positively with critical reflection, and negatively with habitual action? Is anxiety indicative of one's inclination to practice habitual learning?

### *The Emphasis on Academic Engagement and Achievement Outcome*

Situating both habitual action and critical reflection as central constructs in the learning process is significant, theoretically, and may provide fruitful information regarding educational practices for implementation. The quest then, similarly, is for us to explore the potential impacts of habitual action and critical reflection on adaptive outcomes. From a positive, non-deficit perspective, it is important to identify contributors and enhancers of proactive engagement and academic learning in achievement contexts. Stipulating academic engagement as an adaptive outcome, from our point of view, is integral to our understanding of the interrelations between the three antecedents and two internal cognitive processes – for example, the impact of academic buoyancy on critical reflection, which in turn influences academic engagement and achievement outcome. Academic engagement is an important theoretical facet, which has to date been explored extensively by a number of educators and researchers (Pike and Kuh, (2005) and Suarez-Orozco, Pimentel, and Martin, 2009). In its simplistic term, according to Axelson and Flick (2010), academic engagement or student engagement is defined as to ‘how involved or interested students appear to be in their learning and how connected they are to their classes, their institutions, and each other’ and as ‘the degree to which students are ‘connected’ to what is going on in their classes’ (Steinberg, Brown, and Dornbusch, 1996). This schooling construct has been noted to make a major contribution in the prediction of students’ motivation and quality learning in achievement contexts. Indeed, from an educational perspective, Kuh’s (2009) theoretical overview indicates the significance of engagement and how this construct has spanned the course of seven decades.

Existing theoretical tenets (Kember, et al., 2000) seem to indicate that, for instance, habitual action and superficial would reflect a work-avoidance mindset, whereby students are more inclined to disengage and exhibit a number of maladaptive-related attributes. We contend that deep cognitive processes, in contrast, would facilitate proactive behaviors, such as students manifesting more engagement in schooling, consequently as a result of other cognitive-motivational processes. It is plausible to suggest that affective responses, in conjunction with effort expenditure, could associate with critical reflection to motivate and engage students (e.g., critical reflection mobilizes a student to expend more effort in his/her learning, consequently, resulting in engagement. There is some evidence to indicate that both habitual action and critical reflection exert varying effects on achievement-related outcomes. The work of Phan (2009), for example, has provided empirical support, highlighting the positive predictive effect of critical reflection on both quality learning ( $\beta = .70, p < .05$ ) and achievement outcome ( $\beta = .57, p < .05$ ). Leung and Kember’s (2003) study, similarly, yielded a pattern in findings, emphasizing the potency of critical reflection and its association with a deep approach to learning. Habitual action, in contrast, given its nature and characteristics [e.g., automated action with minimal effort and conscious thought: is expected to result in maladaptive practices. We anticipate that this type of superficial cognitive processing would compel many individuals to manifest ‘anti-academic’ behaviors, such as work-avoidance and academic disengagement, in general, towards schooling. Given prior research findings, it was noted that both academic buoyancy and task values could also influence students’ academic engagement, given their attested predictive effects on achievement-related outcomes (Martin and Marsh, 2009; Wigfield, and Eccles, 2000). The valuing of an academic task, based on a perception of utility or interest may compel students to approach learning with a sense of keenness, deliberation, and motivation, thereby embedding themselves more proactively in schooling, etc. Buoyancy, in a similar vein, reflects a sense of resilience, motivating students to persist in the face of setbacks and obstacles. Emotional and

physiological states, according to Bandura (1986), associate inversely with personal self-efficacy and other-related processes. A heightened state of anxiety, for example, is related to one's inefficacy beliefs for learning and self-regulation. This line of evidence, as shown in the work of Pajares (1999), is significant, theoretically, and may extend to the outcome of academic engagement and disengagement. Students who have a high state of anxiety and/or exhibit other affective responses would more likely feel disengaged from classroom learning and schooling, altogether. These students would, similarly, align and demonstrate other negative-related attributes, such as an orientation towards work-avoidance goals. Academic buoyancy Emotional states Task values Habitual action Critical reflection and Academic Engagement Academic achievement.

### ***In Totality: The Impact on Academic Achievement***

The study of quality learning in achievement contexts, overall, entails the inclusion of a number of psychosocial factors and cognitive-motivational constructs for empirical examination. The theoretical-conceptual framework that we formulate reflects the complexity in interrelationships between constructs that could account and explain students' achievements. The preceding sections illustrate an important scope in associations, detailing the possible contributions of three major antecedents: emotional and physiological states, academic buoyancy, and task values. We amalgamated different theoretical orientations (e.g., expectancy-value theory: Wigfield, and Eccles, 2000) and strands of research inquiries within one study for investigation, stipulating in this case four major hypotheses:

- HP1: Emotional and physiological states will exert negative effects on critical reflection, academic engagement and achievement, and a positive effect on habitual action.
- HP2: Both academic buoyancy and task value will exert positive effects on critical reflection, academic engagement, and achievement, and negative effects on habitual action.
- HP3: Habitual action will exert negative effects on academic engagement and achievement, whereas critical reflection will exert positive effects on these two variables.
- HP4: Academic engagement will relate positively with achievement.

Overall, the proposed hypotheses for examination have a number of theoretical and practical merits for consideration. Empirical evidence established may provide a basis for continuing conceptualization and research development within the socio-cultural contexts of the Asia-Pacific region. Notably, one potential aspect for discussion entails the cross-cultural generalizeability of the present theoretical-conceptual model to other Asian countries. How does academic buoyancy make a contribution towards the prediction and enhancement of quality learning of Non-Western students?

## **Method**

### ***Participants***

Participants in the present study were 294 (151 men, 143 women) first-year university students enrolled in Teacher Education courses at a university in Australia. The ages of the students ranged from 18 – 44 ( $Mn = 24.5$ ,  $SD = 1.76$ ).

Participation by the students was voluntary and no remuneration was provided. Students were also instructed to write down their names for the main purpose of identification in terms of their end-of-semester results. Students were assured of anonymity and that their responses would only be seen by the researchers involved in the study. Finally, in relation to answering the questionnaires, the students were asked to situate their responses within the context of the subject Educational Psychology, as they were enrolled in this unit at the time.

### ***Instruments***

*Academic Buoyancy.* Four items from the *Buoyancy Scale* (Martin and Marsh, 2009) was used to measure academic buoyancy. The sample items, self-rated on a 7-point scale (1 (Strongly disagree) to 7 (Strongly agree)), included, for example: “I’m good at dealing with setbacks” and “I don’t let study stress get on top of me”.

**Table 1. Descriptive Statistics of Means and Standard Deviations**

Men	(N = 151)				
Women	(N = 143)				
Total sample	(N = 294)				r
Academic buoyancy	4.485 (1.475)	4.550 (1.457)	4.516 (1.464)		.94
Emotional and Physiological States	2.201 (1.121)	2.219 (1.115)	2.210 (1.117)		.85
Task values	5.713 (1.028)	5.727 (1.004)	5.720 (1.015)		.91
Habitual action	2.219 (1.051)	2.226 (1.024)	2.222 (1.036)		.84
Critical reflection	5.400 (.755)	5.395 (.762)	5.397 (.757)		.65
Academic engagement	5.750 (.888)	5.808 (.839)	5.778 (.863)		.88

- Mean values are numbers outside parentheses
- Standard deviations are numbers in parentheses

Note: Standard deviations are shown in brackets. *Academic Engagement*. There are a number of inventories, which measure and assess students' academic engagement. Given that the focus of the present investigation is grounded in a cognitive-motivational approach, we chose to use Schaufeli, et al.'s (2002) *Engagement Scales*, Student Version, to measure university students' academic engagement. The three subscales, as detailed previously, contain self-report items that emphasize and reflect motivation-related attributes, such as learning engrossment, enthusiasm, resilience, and effort expenditure. The Engagement Scales, overall, have been found to demonstrate good construct validity, relevance, and applicability to classroom learning (Schaufeli, et al., 2002). The 17 items, answered on a 7-point rating scale (1 (Strongly disagree) to 7 (Strongly agree), defined three distinct dimensions of engagement: *Vigor* (e.g., "When I get up in the morning, I feel like going to [lectures] and [tutorial] classes"), *Dedication* (e.g., "To me, my studies [at university] are challenging"), and *Absorption* (e.g., "When I am studying, I forget everything around me"). We also modified the wordings of some items to suit university learning contexts. This revision has been validated in our previous research, which has been published recently [61]. *Emotional and Physiological State*. We adapted the emotional and physiological states subscale of previous inventories [62, 63] to measure students' emotional and physiological states. The six items, rated on a 7-point rating scale (1 (Definitely disagree) to 7 (Definitely agree), included, for example: "This subject, educational psychology, makes me stressed and nervous" (Emotional and physiological states). *Habitual Action and Critical Reflection*. Both cognitive processing types were measured using Kember, et al.'s (2000) Reflective Thinking Questionnaire (RTQ). The RTQ contains 16 items, defining four major subscales: Habitual Action, Understanding, Reflection, and Critical Reflection. For this study, we used the Habitual Action and Critical Reflection subscales, with each subscale containing four items rated on 7-point rating scale (1 (strong disagree) to 7 (strongly agree)). The sample items included, for example: "When I am working on some activities, I can do them without thinking about what I am doing" (Habitual Action) and "As a result of this unit, educational psychology, I have changed the way I look at myself" (Critical Reflection). *Task Values*. We used the task value subscale of the Motivated Strategies for Learning Questionnaire (MLSQ) (Pintrich, et al., 1993) to measure task values. The subscale, containing six items measured on a 7-point rating scale (Strongly disagree) to 7 (Strongly agree), describes values pertaining to interest (e.g., "I am very interested in the content area of this subject, educational psychology"), perceived usefulness (e.g., "I think I will be able to use what I learn in this subject, educational

psychology, in other subjects”), and importance (e.g., “It is important for me to learn the subject material in this class”). Academic achievement was measured by collating students’ unit mark at the end of the semester. The unit that the students enrolled does not have a formal final exam, but rather entailed continuous assessment tasks (e.g., Reading response task). There is, however, an end-of-semester quiz (20%), which consists of multiple-choice, true/false, and matching questions for answering.

**Results**

We used structural equation modeling (SEM) to test the hypothesized *a priori* model described. This statistical technique emphasizes the importance of both latent factors and measured indicators, whereby the latter is assumed to have true errors (i.e.,  $E \neq 0$ ). Unlike other multivariate statistical techniques, SEM enables researchers to test and compare competing *a priori* models. The statistical software packages SPSS21 and SPSSAMOS 20 were used to assist in the descriptive and latent variables analyses. Following the protocols that have been established previously (Byrne, 2010, Kline, 2011, Schumacker and Lomax, 2004), we used covariance matrices and maximum likelihood solutions. Maximum likelihood procedure, similarly, has been noted to perform reasonably well when data are normally distributed [68]. In relation to the goodness-of-fit index values, the following were chosen: (i) the chi-square statistics (2) and degree of freedom (d), (ii) Comparative Fit Index (CFI)(CFI .90), (iii) the Non-normed Fit Index (NNFI)(NNFI .90), and (iv) the Root Mean Square Error of Approximation(RMSEA)(RMSEA .080). Finally, Cronbach’s alpha (Education Journal 2014) values and descriptive statistics, involving the means and standard deviations for the total sample and individual groups (men versus women) are presented in Table 1. Table2, similarly, presents the correlations among variables involved in the model for statistical testing.

**Table 2. Correlations between Variables**

**Variables 1 2 3 4 5 6 7**

1. Academic buoyancy	1.00						
2. Emotional states	.041	1.00					
3. Task values	.116 *	.016	1.00				
4. Habitual action	.163 **	.434 **	-.049	1.00			
5. Critical reflection	-.004	-.001	.078	.053	1.00		
6. Academic engagement	-.055	.133 *	.266 **	.136 *	.034	1.00	
7. Academic achievement	.068	-.016	.152 **	.106	.158 **	.463 **	1.00

Note: \*  $p < .05$ , \*\*  $p < .01$

**Structural Relations between the Variables**

We tested a number of *a priori* models that reflected the hypotheses mentioned previously. Specifically, in relation to Figure 1, we focused on two major types of structural paths – paths that originated from emotional and physiological states, academic buoyancy, and task values to habitual action and critical reflection, and paths that originated from habitual action and critical reflection to academic engagement and achievement outcome. The first model we tested, Model M1, denoted the hypothesized model with the exception of the following structural paths, which

we did not include: (i) habitual action to academic engagement and achievement, critical reflection to academic engagement and achievement, (ii) task value to habitual action, and (iii) academic buoyancy to habitual action. The initial test showed that the data fitted the hypothesized model relatively well:  $\chi^2/d = 3.215$ ,  $p < .001$ , CFI = .905, RMSEA = .087. Continuing on with the initial model, we progressively included structural paths for statistical testing in order to ascertain an appropriate model fit. The Model M1 was extended, which included the possible negative effects of habitual action on academic engagement and achievement, and the possible positive effects of critical reflection on these two adaptive outcomes. Including these four structural paths yielded an improvement in model fit for this model, ModelM2:  $\chi^2/d = 3.195$ ,  $p < .001$ , CFI = .908, RMSEA = .087. A final model for statistical testing, an extension of Model M2, included the structural paths from both task values and academic buoyancy to habitual action. ModelM3, generated a small improvement in model fit, compared to Models M1andM2 ( $\chi^2/d = 3.186$ ,  $p < .001$ , CFI = .910, RMSEA = .085). These goodness-of-fit index values, were acknowledge, to be relatively modest at best, and do not indicate an optimal fit (Loehlin, (2004). Having said this, however, the complexity of the statistical models (e.g., 21 measured indicators, 6 latent factors), is believed, to have also accounted for the moderate model fit produced. A summary of the goodness-of-fit index values for the three models tested is presented in Table 3. Chi-square difference tests, which was subsequently conducted, yielded evidence of acceptance for a more parsimonious model – in this case, Model M3( $\chi^2(M2 - M3) = 7.99$ ,  $p .025$ ). The final solution for discussion, Model M3, does support the hypothesized model. For clarity, the non-statistical significant paths from this visual representation have been omitted. All standardized structural paths are significant at the  $p < .05$  and  $p < .01$ . Factor loadings are significant at the  $p < .001$  and these ranged from .741 to .223 ( $Mn = .791$ ,  $SD = .039$ ) for academic buoyancy, .595 to .837 ( $Mn = .712$ ,  $SD = .121$ ) for emotional and physiological states, .759 to .815 ( $Mn = .787$ ,  $SD = .028$ ) for task values, .400 to .963 ( $Mn = .762$   $SD = .248$ ) for habitual action, .587 to .927 ( $Mn = .813$ ,  $SD= .158$ ) for critical reflection, and .622 to .778

**Table 3. Goodness-of-fit Index Values**

Model M1with the freeing of structural paths from:

TV to CR; TV to AE; TV to AA; AB to CR; AB to AE; AB to AA; EP to HA; EP to CR; EP to AE; EP to AC; 620.519 193 .887 .905 .087

Model M2Model M1with the inclusion of the following structural paths from:

HA to AE; HA to AA; CR to AE;

603.834 189 .888 .908 .087

CR to AA

Model M3Model M2with the freeing of structural paths from:

TV to HA; AB to HA

595.835 187 .899 .910 .085

Note: AA = Academic achievement, AB = Academic buoyancy, AE =Academic engagement, CR = Critical reflection, EP = Emotional and physiological states, HA = Habitual action, CR =

Critical reflection. ( $Mn = .685$ ,  $SD = .082$ ) for academic engagement. It is interesting to note that for the hypothesized associations between the three antecedents (e.g., academic buoyancy and task values), only the association between academic buoyancy and task value is statistical significant ( $\beta = .124$ ,  $p < .05$ ).

### ***Direct and Indirect Effects***

In addition, a decomposition in direct and indirect effects is shown below. There are, in total, 13 statistical significant direct and indirect paths. For the direct effects, it was noted that the three antecedents were influential in their predictive effects: (i) both emotional and physiological states ( $\beta = .410$ ,  $p < .001$ ) and academic buoyancy ( $\beta = .140$ ,  $p < .05$ ) influenced habitual action, whereas task values influenced critical reflection ( $\beta = .146$ ,  $p < .05$ ) and academic engagement ( $\beta = .327$ ,  $p < .001$ ). Habitual action also exerted a positive effect on academic engagement ( $\beta = .138$ ,  $p < .05$ ), whereas both academic engagement ( $\beta = .541$ ,  $p < .001$ ) and critical reflection ( $\beta = .186$ ,  $p < .001$ ) influenced academic achievement. In terms of indirect effects, in contrast, academic engagement was influenced by emotional and physiological states ( $\beta = .053$ ,  $p < .05$ ), academic buoyancy ( $\beta = .023$ ,  $p < .05$ ), and task values ( $\beta = -.024$ ,  $p < .05$ ), via habitual action. Habitual action also influenced academic achievement ( $\beta = .075$ ,  $p < .05$ ), via engagement, whereas emotional and physiological states ( $\beta = .114$ ,  $p < .025$ ) and buoyancy ( $\beta = -.056$ ,  $p < .05$ ) influenced academic achievement, via habitual action and engagement. Finally, task values influenced academic achievement ( $\beta = .189$ ,  $p < .001$ ), via critical reflection and engagement.

### **Discussion**

The study of quality learning in achievement settings is an important feat for accomplishment. This avenue of research inquiry is significant, especially in light of our interest to explore the cognitive-motivational nature of students' learning and its potentials for discussion and research development in the socio-cultural contexts of the Asia-Pacific region. The present study is significant for its conceptualization, detailing the sequential interrelations between antecedents, cognitive processes, and adaptive outcomes. Drawing from existing theoretical tenets (e.g., social cognitive theory; academic engagement: Schaufeli, et al., 2002; Suarez-Orozco, et al., 2009) and empirical evidence, a framework that scoped a number of research hypotheses for statistical testing was developed. The results obtained, in general, support the potency of academic buoyancy, emotional and physiological states, and task values as predictive antecedents of cognitive and adaptive outcomes (e.g., academic engagement). In this section of the article, we discuss the present findings with reference to potential educational practices and continuing research development.

### ***The Potency of Antecedents: What Do they Do***

A notable finding from the present study indicates the predictiveness of academic buoyancy (i.e., impacting on habitual action), emotional and physiological states (i.e. impacting on habitual action), and task values (i.e. impacting on critical reflection and academic engagement). Situating within the framework of social cognition (Bandura, 1986), we hypothesized that various constructs would make contributions in the prediction of cognitive processes (e.g. critical reflection) and adaptive outcomes (e.g., academic engagement). This theoretical positioning contends there are antecedents that could interact to influence students' learning and achievement-related outcomes. Previous research (Martin and Marsh, 2008a; Diseth, 2011; and

Liem, et al., 2008). has, for example, detailed the connectedness of cognitive (e.g., deep cognitive processing) and non-cognitive (e.g., personal self-efficacy) constructs in academic learning. Academic buoyancy, as expected, influenced students' habitual action and automated learning. What is surprising, however, is the fact that buoyancy is related positively with one's superficial and automated learning. Emotional and physiological states (e.g., a heightened state of anxiety), consistent with the work of Bandura (1986) and existing studies (Pajares, Miller, and Johnson, 1999), reflect positively with one's inclination towards habitual action and automated learning. Students who express high emotional and physiological states (e.g., anxiety) would tend to exhibit more preference towards superficial learning and study habits and behaviors that reflect a sense of work-avoidant and non-serious practices. The validation in structural relations for task values is consistent with previous proposition, and supports existing theoretical tenets and research studies (Liem, et al, (2008), Eccles, et al., 1983). Evidence ascertained in the present study illuminates the potent effects of task values (e.g., utility value) on both critical reflection and academic engagement. The predictive contribution of task values on achievement-related outcomes, in particular, emphasizes its role as an effective antecedent. Encouraging critical reflection [e.g., "As a result of this course I have changed the way I look at myself" in educational contexts may involve, in this case, the use of task values, situated within expectancy-value theories (Eccles, et al., 1983 & Wigfield and Eccles, 2000). Structuring learning tasks and activities that emphasize the notion of importance and perceived usefulness may, in this instance, stimulate curiosity, subject interest, and excitement, thereby instilling a mindset towards critical reflection and academic engagement. Task values, in this case, may facilitate an approach that reflects mastery and intrinsic motivation, enabling students to think beyond the acquiring of knowledge simply for assessment purposes.

**Table 4. Decomposition of Effects: Direct, Indirect, and Total.**

**Predictor Outcome Direct Indirect Total**

Academic buoyancy	Habitual action	.140 *	.000	.140 *
Emotional and physiological states		.410 ***	.000	.410 ***
Task values		-.099	.000	-.099
Academic buoyancy	Critical reflection	-.052	.000	-.052
Emotional and physiological states		.044	.000	.044
Task values		.146 *	.000	.146 *
Habitual action	Academic engagement	.138 *	.000	.138 *
Critical reflection		-.073	.000	-.073
Academic buoyancy		-.113	.023 *	-.090
Emotional and physiological states		.127	.053 *	.180
Task values		.327 ***	-.024 *	.303 ***
Academic engagement	Achievement	.541 ***	.000	.541 ***
Habitual action		.021	.075 *	.096
Critical reflection		.186 ***	-.039	.147 ***
Academic buoyancy		.102	-.056 *	.046
Emotional and physiological states		-.111	.114 **	.003
Task values		-.031	.189 ***	.158

Note: \*\*  $p < .01$ , \*\*\*  $p < .001$ .

It was noted that critical reflection also exerted a positive effect on academic achievement (e.g., critical reflection achievement,  $\beta = .186$ ,  $p < .001$ ). The established association between critical reflection and academic achievement is consistent with findings obtained previously (Leung and Kember, 2003), and highlights the predictive and explanatory power of critical reflection. This finding pertaining to the central role of critical reflection entails a number of implications for applied educational practices. Critical reflection, in this analysis, may impart and/or associate with achievement-related attributes (e.g., deep cognitive processing) that could, in turn, result in the enhancement of academic learning. This cognitive process construct, of course, reflects a high-order level of reflection (Kember, et al., (2000), requiring personal experience, effort, and motivation. Some students in classroom situations may embrace in superficial thinking and habitual practices (e.g., "If I follow what the lecturer says, I do not have to think too much on this course") given their limited knowledge and experiences, lack of confidence, and/or motivation, the positive effect of critical reflection indicates that there is an important need for educators to consider. A heightened sense of critical reflection enables students to achieve and excel, academically. Strategies to encourage and foster this practice of critical reflection may include, in this case, the use of task values and other motivational means (e.g., instilling personal self-efficacy). Subject contents and learning activities that stimulate intellectual curiosity and interest may, in this analysis, instill authenticity, meaning, and purpose to learning (e.g., Why am I doing this subject and what implications does it have for me in terms of my future aspirations?).

## Conclusion

The correlational investigation detailed in this article has contributed, overall, to the study of students' learning in achievement contexts. Evidence ascertained from causal modeling procedures supports the theoretical-conceptual model and research hypotheses relating to the intricate associations between cognitive, motivational, and adaptive outcomes. Empirically, in terms of advancement and continuing research development, the researchers have established some notable trajectories that scoped the effects of three psychological antecedents on cognitive processes and adaptive outcomes. Researchers are encouraged to explore the mentioned avenue of inquiry and its respective findings with other educational levels and/or cultural samples.

## Recommendations

1. The researchers recommend that there should be active participation in university learning and related activities which may feature prominently in terms of nation building, enabling students to contribute to the social and economic fabrics of society.
2. Educators should endeavour to consider students' mastery and performance –based approaches to academic learning by encouraging positive outcomes rather than making attempts to resolve potential detrimental consequences, which had been found to be more cost-effective and has a number of educational and social benefits.
3. Educators and researchers should invest intellectual capitals and resources into favorable outcomes for students by promoting a heightened state of self-efficacy.
4. Also, pedagogical strategies, extraneous psychosocial factors, and instructional policies that could enhance students' academic engagement should be considered.

5. A perceived sense of usefulness of a learning task for future aspirations, or the appreciation of learning for intrinsic motives would, in this sense, motivate students towards academia and learning, in general.
